

BOM/DOM, jQuery, and Ajax

Dr. Hale

University of Nebraska at Omaha

Secure Web Application Development – Lecture 5

Today's topics:

BOM/DOM Overview

- In more detail

- How is it used for javascripting

jQuery

- Basic syntax overview

- jQuery selectors

- Functions and effects

- Animation

- Event handling

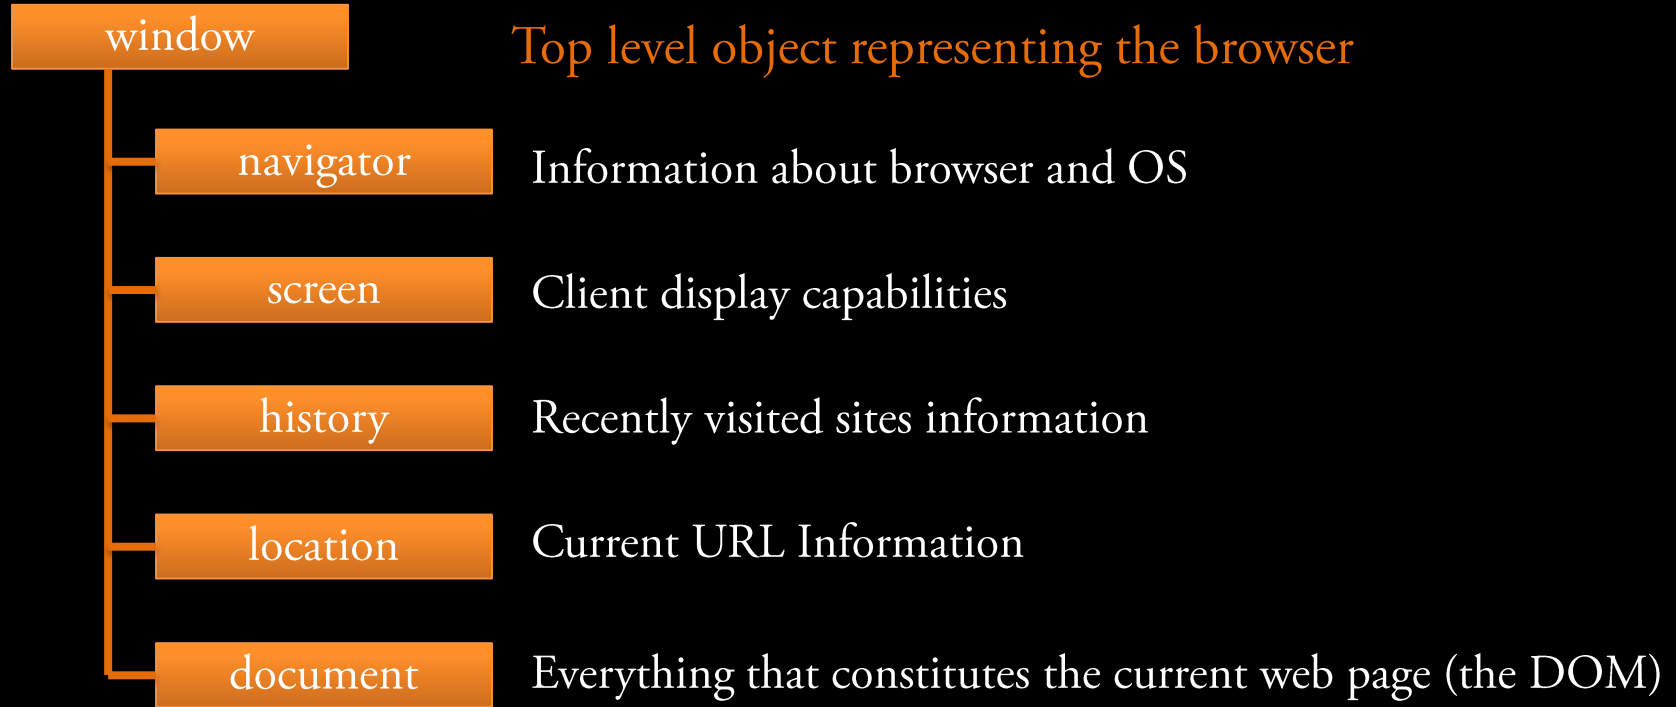

Ajax

- Callbacks and Ajax

- Promises and Ember integration

BOM/DOM

Browser Object Model

B O M

O v e r v i e w

a little 'history'

- Until recently different browsers implemented the BOM differently
 - to the bane of every web developer ever
 - increasing standardization these days has led a ubiquitous BOM (finally)
- The BOM is the browsers API

Property	Description
appName	Returns the code name of the browser
appVersion	Returns the name of the browser
cookieEnabled	Returns the version information of the browser
language	Determines whether cookies are enabled in the browser
onLine	Returns the language of the browser
platform	Determines whether the browser is online
product	Determines for which platform the browser is compiled
userAgent	Returns the engine name of the browser
	Returns the user-agent header sent by the browser to the server

Note: Methods are linked to w3c definitions if viewing online

Property	Description
availHeight	Returns the height of the screen (excluding the Windows Taskbar)
availWidth	Returns the width of the screen (excluding the Windows Taskbar)
colorDepth	Returns the bit depth of the color palette for displaying images
height	Returns the total height of the screen
pixelDepth	Returns the color resolution (in bits per pixel) of the screen
width	Returns the total width of the screen

Note: Methods are linked to w3c definitions if viewing online

Property	Description
length	Returns the number of URLs in the history list

Method	Description
back()	Loads the previous URL in the history list
forward()	Loads the next URL in the history list
go()	Loads a specific URL from the history list

Note: Methods are linked to w3c definitions if viewing online

Property	Description
hash	Sets or returns the anchor part (#) of a URL
host	Sets or returns the hostname and port number of a URL
hostname	Sets or returns the hostname of a URL
href	Sets or returns the entire URL
origin	Returns the protocol, hostname and port number of a URL
pathname	Sets or returns the path name of a URL
port	Sets or returns the port number of a URL
protocol	Sets or returns the protocol of a URL
search	Sets or returns the querystring part of a URL

Note: Methods are linked to w3c definitions if viewing online

DOM Level 1 Object Model

Method	Description
assign()	Loads a new document
reload()	Reloads the current document
replace()	Replaces the current document with a new one

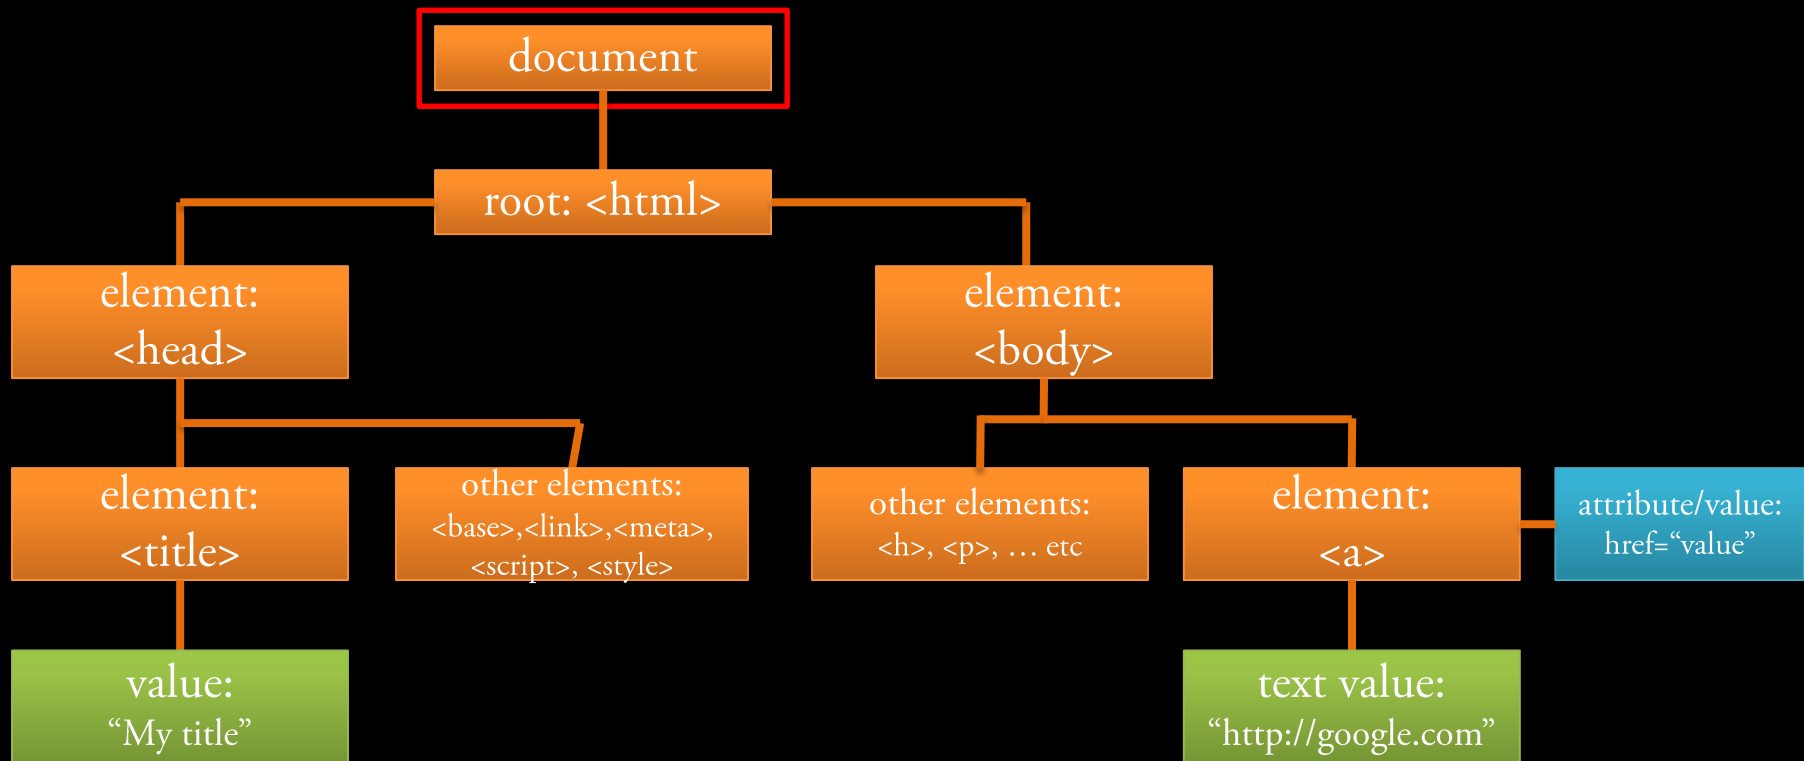

Note: Methods are linked to w3c definitions if viewing online

IT'S A TREE!

elements

- may have attributes
 - id, name, href, {{inert your own}}
- may have values
 - text, images, javascript, etc
- are composable
 - can be nested in different ways hierarchically

Example:

`Link to Google`

element

value

attribute / value

`<p id="section1" style="some CSS;">Here is a block of text with an emphasis on examples. </p>`

nodes/parents/siblings

- each item can be seen as a 'node'
- Using this hierarchy, javascript can iterate over nodes, parents, and siblings
- e.g., `em.parentNode` (referencing the `em` below) would return the `p` element
- `p.nodeValue` would return the combined text and `em` blocks

element

value

attribute / value

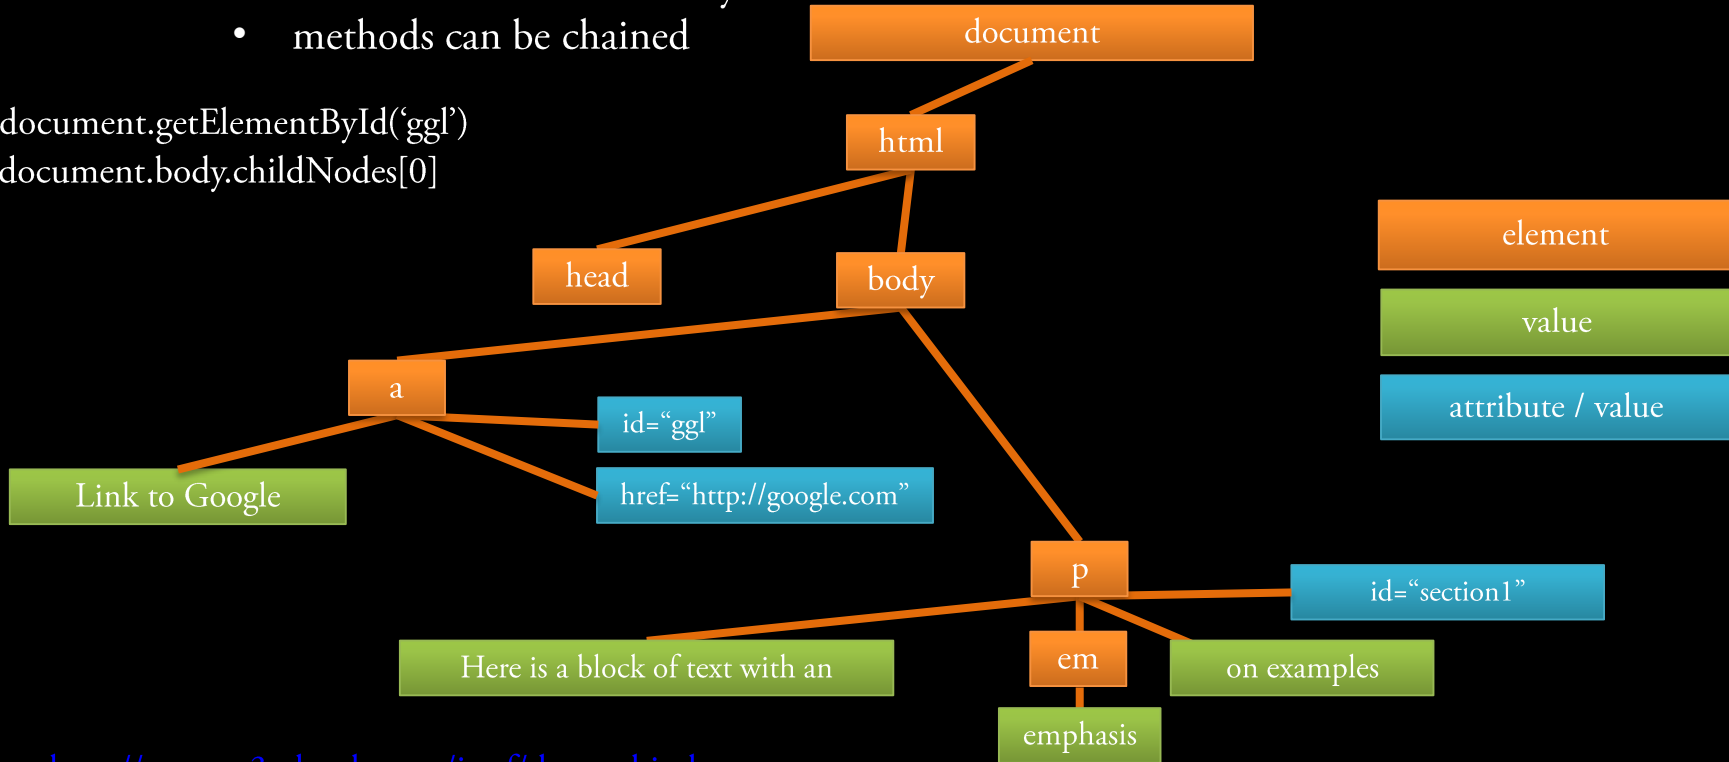

`<p id="section1" style="some CSS;">Here is a block of text with an emphasis on examples. </p>`

nodes (con't)

- can be referenced by type, id, etc
- can be traced hierarchically
- methods can be chained

`document.getElementById('ggl')`
`document.body.childNodes[0]`

refer to: http://www.w3schools.com/jsref/dom_obj_document.asp
for methods/properties of the **document** object

You've been using the DOM in ember all along.

Learn How to Use 'Magic'

Overview

- jQuery is a library of javascript (JS) functions
- wraps basic DOM capabilities to
 - access DOM
 - modify DOM
 - animate elements
 - handle events
 - manage in-page server-side connections
- provides browser-independence for JS

Overview (con't)

- jQuery is open source and free
- massive community resources
- two versions
 - jquery-version-number.min.js (minified) – use for production
 - jquery-version-number.js (development) – use for coding
- easily included in your project (in head or body, body is best for speed)
 - `<script src="../../path-to-js-directory/jquery-version-number.js"></script>`

<http://jquery.com/>

Philosophy

Facilitate interactions between javascript and HTML

(basically) Find DOM element → do something to it

Syntax

`$(selector).action()`

- The `$` symbol is the jQuery namespace (analogous to a package in java)
- the `(selector)` is the query that locates DOM element(s)
- An `action()` is a composable sequence of functions to apply to the selected elements.

Examples

- `$(“p”).html(“some text”)` – overwrite all `<p>` elements in the document to state ‘some text’
- `$(“#content”).fadeOut()` – hide the element with id “content” using an animated fade effect
- `$(“#content”).fadeTo(1000,.5)` – change opacity of element with id content to 50% over a 1000ms time interval
- `$(“.row”).hide()` – hide all elements with a class attribute named “row”
- `$(“.row”).width(“600px”)` – change the ‘width’ property of all elements with a class named ‘row’

NOTE: DEMO EET on jQuery page

Unpacking the Syntax

Basic Javascript

```
var c = document.getElementById('content');  
c.innerHTML = 'test';
```

jQuery

```
$("#content").html('test');
```

NOTE: jQuery may implement multiple versions to handle different browser types

Whats up with the \$ (bills)

- jQuery(args) is a selector function
- \$ is a variable name in the global window space that references jQuery

i.e.

```
var $ = jQuery;
```

Hence

```
$("p").html("some text")
```

is equivalent to

```
jQuery("p").html("some text")
```

More on \$(selector)

Selector can be:

- a CSS selector expression (all of examples shown so far)
- a string of HTML e.g., \$(:contains('some html'))
- a javascript object e.g., \$(myVar)

Most developers basically will only use the first type

More on \$(selector)

Selectors are tiered, chainable, composable, and can use DOM properties

(Tiered) `$("#content h2")`

//all <h2> elements under any element with id 'content'

(Chain) `$("h2.block:contains('What is jQuery')")`

//all <h2> elements with class block that contains the string 'What is jQuery'

(Composed) `$("h2.block:contains('What is jQuery'), section.project-tiles")`

//the (chain) dom elements plus all <section> elements of class "project-tiles"

(DOM OPs) `$("#corporate-members li:last-child")`

//the last element under an element with id 'corporate-members'

\$(selector) Summary

j
Q
u
e
r
y

M
a
g
i
c

Syntax	Selector description
\$("#*")	All elements
\$("#this")	Current HTML element (useful for iteration or buttons)
\$("#element")	Element Selector: All elements of type 'element'
\$("#.class")	Class Selector: All elements with class 'class'
\$("#[attribute]")	Attribute Selector: All elements with attribute 'attribute'
\$("#:dom-prop")	DOM methods: All elements matching the dom property 'dom-prop'
\$("#e1, e2")	Composed selector: all elements of type e1 or e2
\$(myVar)	Object Selector: Javascript object named myVar
\$(contains('string'))	String Selector: All elements that contain the 'string'

`.action()` Simple Effects and Animation

jQuery comes equipped with a good variety of out of the box capabilities

- Display: `hide()` / `show()` / `toggle()` / `slideUp()` / `slideDown()` / `slideToggle()`
- Opacity: `fadeIn` / `fadeOut()` / `fadeTo()` / `fadeToggle()`
- Custom: `animate()` / `stop()` / `delay()` / `finish()` / `clearQueue()` / `dequeue()` / `myFunction()`

.action() Display hide/show

jQuery makes hiding and showing elements easy

- Can be used for menuing, content queuing, rendering improvement, data loading, etc
- Hide / show – no frills basics

[.hide\(\[duration \] \[, complete \] \)](#)

duration (default: 400)

Type: [Number](#) or [String](#)

A string or number determining how long the animation will run.

complete

Type: [Function\(\)](#)

A function to call once the animation is complete.

[.show\(\[duration \] \[, complete \] \)](#)

duration (default: 400)

Type: [Number](#) or [String](#)

A string or number determining how long the animation will run.

complete

Type: [Function\(\)](#)

A function to call once the animation is complete.

.action() Display slideUp/slideDown

jQuery makes hiding and showing elements easy

- Can be used for menuing, content queuing, rendering improvement, data loading, etc
- slideUp / slideDown – accordion-like hide/show functionality

[.slideDown\(\[duration \] \[, complete \] \)](#)

duration (default: 400)

Type: [Number](#) or [String](#)

A string or number determining how long the animation will run.

complete

Type: [Function\(\)](#)

A function to call once the animation is complete.

[.slideUp\(\[duration \] \[, complete \] \)](#)

duration (default: 400)

Type: [Number](#) or [String](#)

A string or number determining how long the animation will run.

complete

Type: [Function\(\)](#)

A function to call once the animation is complete.

.action() Display slideUp/slideDown

jQuery makes hiding and showing elements easy

- Can be used for menuing, content queuing, rendering improvement, data loading, etc
- slideUp / slideDown – accordion-like hide/show functionality

.slideDown([duration] [, complete])

duration (default: 400)

Type: [Number](#) or [String](#)

A string or number determining how long the animation will run.

complete

Type: [Function\(\)](#)

A function to call once the animation is complete.

.slideUp([duration] [, complete])

duration (default: 400)

Type: [Number](#) or [String](#)

A string or number determining how long the animation will run.

complete

Type: [Function\(\)](#)

A function to call once the animation is complete.

.action() Opacity fadeIn/fadeOut/fadeTo

jQuery makes hiding and showing elements easy

- Can be used for menuing, content queuing, rendering improvement, data loading, etc
- fadeIn/fadeOut – adjust transparency entirely to 0 or 1
- fadeTo – adjust transparency to a specific value

[.fadeIn\(\[duration \] \[, complete \] \)](#)

duration (default: 400)

Type: [Number](#) or [String](#)

A string or number determining how long the animation will run.

complete

Type: [Function](#)()

A function to call once the animation is complete.

[.fadeOut\(\[duration \] \[, complete \] \)](#)

duration (default: 400)

Type: [Number](#) or [String](#)

A string or number determining how long the animation will run.

complete

Type: [Function](#)()

A function to call once the animation is complete.

[.fadeTo\(duration, opacity \[, complete \] \)](#)

duration Type: [String](#) or [Number](#)

A string or number determining how long the animation will run.

opacity Type: [Number](#)

A number between 0 and 1 denoting the target opacity.

complete Type: [Function](#)()

A function to call once the animation is complete.

j
Q
u
e
r
y

M
a
g
i
c

.action() Animate

Custom animations using CSS

[.animate\(properties \[, duration \] \[, easing \] \[, complete \] \)](#)

properties

Type: [PlainObject](#)

An object of CSS properties and values that the animation will move toward.

duration (default: 400)

Type: [Number](#) or [String](#)

A string or number determining how long the animation will run.

easing (default: swing)

Type: [String](#)

A string indicating which easing function to use for the transition.

complete

Type: [Function](#)()

A function to call once the animation is complete

NOTE: can only be applied to positioned elements (fixed, absolute or relative)

.action() Chaining

You can chain multiple actions

j
Q
u
e
r
y

```
$("#h2").hide().html("some text").fadeIn(1000)
```

M
a
g
i
c

`.action()` Eventing

jQuery provides an event system that allows for handling and triggering

- Can 'bind' event handlers to DOM elements
- Handlers can be any function
- Can 'trigger' events on elements programmatically (within browser scripting constraints)

`.action()` Eventing

Binding event handlers

```
$().ready(function() {  
    $("h2").click(function() {  
        alert('test');  
    });  
});
```

```
window.onload = init;  
function init() {  
    var es = document.getElementsByTagName('h2')  
    for (var i == 0; i <= es.length; i++) {  
        es[i].onclick = function() {alert('test')}  
    }  
}
```

`.action()` Eventing

Binding custom events and triggering the event handlers programmatically

```
$().ready(function() {  
    $("h2").click(function() {  
        alert('test');  
    });  
});
```

`$("h2:first").trigger("click")`

```
$().ready(function() {  
    $('element').bind('event-type', function() {  
        alert('test bind');  
    });  
});
```

`$(“element”).trigger(“event-type”)`

.action() Eventing

Some built in events

Event

Description

<code>.error()</code>	Browser event that handles errors (can be HTTP, such as 404 for imgs)
<code>.resize()</code>	Browser event triggered on resize
<code>.scroll()</code>	Browser event triggered on scrolling
<code>.load()</code> , <code>.ready()</code> , <code>.unload()</code>	Document loading methods that signal when the DOM is loaded, ready, or unloaded
<code>.blur()</code> , <code>.change()</code> , <code>.focus()</code> , <code>.focusin()</code> , <code>.select()</code> , <code>.submit()</code>	Form event handlers that handle blurring, changing, focusing, selecting, or submitting form elements
<code>.focusout()</code> , <code>keydown()</code> , <code>keypress()</code> , <code>keyup()</code>	Keyboard event handlers that handle moving out of an element, an event when the key is first down, the press event, and the event when the key is first up
<code>.click()</code> , <code>.dblclick()</code> , <code>.focusout()</code> , <code>.hover()</code> , <code>.mousedown()</code> , <code>.mouseenter()</code> , <code>.mouseleave()</code> , <code>.mousemove()</code> , <code>.mouseout()</code> , <code>.mouseover()</code> , <code>.mouseup()</code> , <code>.toggle()</code>	Mouse event handlers for dealing with different events related to using a mouse or touchpad. Note there are additional built in handlers for jquery-mobile (e.g., <code>swipeleft()</code> , <code>swiperight()</code>).

j
Q
u
e
r
y

M
a
g
i
c

`.action()` Eventing is messy

As you can imagine this gets messy and begins to look like spaghetti (keep in mind)

```
$().ready(function() {  
    $("h2").click(function() {  
        alert('test');  
    });  
    $(".button").click( function() { // handle ALL button clicks  
        if( $(this).is("#btn1") { // $(this) is current element  
            // code for handling btn1 goes here...  
        }  
        if( $(this).is("#btn2") {  
            // code for handling btn2 goes here...  
        }  
    });  
    ...  
    $(".some other element").bind("some event", function(){  
        //a bunch of other handlers go here  
    })  
});
```

`.action()` Eventing is messy

To add to the mess you can also have handlers directly on elements!

```
<a href="https://someurl.com" onmouseover="somefunction()">Some link text</a>
```

Now you have event handlers potentially everywhere and no clear idea of structuring or modularity except for some comment blocks.

Callbacks

jQuery allows for actions to have a callback function

- A 'callback' gets executed after the action or event completes
- Ex. Return to the hide action, add a callback

`.hide([duration] [, complete])`

duration (default: 400)

Type: [Number](#) or [String](#)

A string or number determining how long the animation will run.

complete

Type: [Function](#)()

A function to call once the animation is complete.

```
$(“h2”).hide(function(){  
    alert(‘hid: ’+ this.innerHTML)  
});
```

Ajax

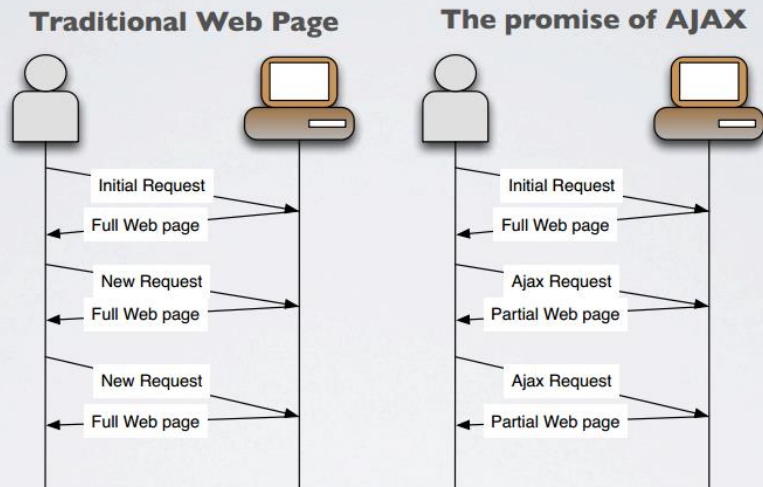

jQuery provides a method called `.ajax()`

- Ajax maps to an XMLHttpRequest action in javascript
- The browser interprets an XMLHttpRequest (aka XHR) according to its implementation
 - jQuery wraps these implementations – so that calling is cross-platform
- As of jQuery 1.5 all `.ajax()` calls implement the Promise interface giving them the methods and behaviors of a Deferred object in jQuery
- This is good because you can chain callback functions using `.then()`, `.done()`, `.fail()`, and `.always()`

Ajax (con't)

Core idea

A
j
a
x

Ajax (con't)

Specifics

A
j
a
x

- Ajax can return different content types including files, images, html, text/javascript, and JSON/XML/YAML
- Can set the http parameters associated with the request
- Can make GET/POST/PUT/DELETE/etc requests with ajax
- Can capture returned data in a callback function
- Can be used to interact with a REST API and then load data into the DOM

Ajax (con't)

Specifics

A
j
a
x

- Ajax can return different content types including files, images, html, text/javascript, and JSON/XML/YAML
- Can set the http parameters associated with the request
- Can make GET/POST/PUT/DELETE/etc requests with ajax
- Can capture returned data in a callback function
- Can be used to interact with a REST API and then load data into the DOM
- Is subject to all the same constraints as other http requests
- Uses a cookie by default on each request
- Is one of the most import areas to focus on for clientside security

Ajax (con't)

Syntax

```
$.ajax(  
    {  
        url: "some-url",  
        type: "GET/PUT/POST/etc",  
        data: myData,  
        other-settings  
    }  
).done(function(data) {  
    //callback function returns response as `data`  
});
```

[jQuery.ajax\(url \[, settings \] \)](#)

url

Type: [String](#)

A string containing the URL to which the request is sent.

settings

Type: [PlainObject](#)

A set of key/value pairs that configure the Ajax request. All settings are optional. A default can be set for any option with [\\$.ajaxSetup\(\)](#).

See [jQuery.ajax\(settings \)](#) below for a complete list of all settings.

A
j
a
x

Ajax (con't)

Example

A
j
a
x

```
$.ajax(  
    {url:"http://jquery.com/browser-support/"}  
).done(function(data){  
    $("#content").append(data)  
});
```

Promises

Definition:

Promises are, in a nut shell, better versions of asynchronous callbacks that exist in one of three states: **pending**, **fulfilled**, or **rejected**

Promises

Ember uses a promise library called `rsvp.js` that lets you create your own promises. Ember data uses promises by default as well.

```
var promise = new RSVP.Promise(function (fulfill, reject){
    //do stuff
});

//invoke the promise
promise.then(function(foo){
    //it worked
}, function(bar){
    //it failed
});
```

Read more: <http://www.toptal.com/javascript/javascript-promises>

Ember search posts example

```
return this.store.find('forumpost').then(function(items) {
    //data loaded
    var filteredItems = items.filterProperty('url',params.searchquery);
    if(filteredItems.length>=1){
        return filteredItems;
    }
    else{
        t.transitionTo('page404');
    }
}, function(errors){
    //dataload failed
    console.log(errors);
});
```

Read more: <http://www.toptal.com/javascript/javascript-promises>

Ember search posts example: no ember data

```
return Ember.$.getJSON('/api/forumposts').then(function(items) {
    //data loaded
    var filteredItems = items.filterProperty('url',params.searchquery);
    if(filteredItems.length>=1){
        return filteredItems;
    }
    else{
        t.transitionTo('page404');
    }
}, function(errors){
    //dataload failed
    console.log(errors);
});
```
